The Opportunity

A production facility had areas on elevated mezzanines that needed to be secured, and the production area had different safety needs than the pallet drop areas. One area was configured for loads up to three pallets wide, while others had tall loads that needed to be fed into a production platform. In addition, some of the gates needed to be power operated so the fork lift truck drivers could control the gates from below.

The Solution

Multiple designs of the Roly® safety gates were created to meet the facility's different requirements in its pallet drop and production areas. An extra tall version of the Roly gate was created for the production platform, which allowed tall loads to be easily and safely loaded and unloaded to the area while keeping employees from falling from the ledge. The dual-gate safety system's gates open and close within the confines of the gate structure, which helped to avoid obstruction into the

production area.

The Roly gates were configured differently for the facility's pallet drop areas. Gates were configured in extra wide designs to fit the three pallet width requirements, and other gates were created to fit extra deep loads. All of the safety gates in the pallet drop areas were configured with power operation that allowed the fork lift truck drivers to operate the gates from the ground level.
